

BindingGYM — DMS_score distribution by whether a variant touches a binding site (density-normalised per assay; vertical lines = group medians)

DMS_score (independent scale per panel; higher = better binding) · panels sorted by Cliff's δ ; grey title = one group empty, not comparable · black dashed line = wild-type score
 OVL = overlap coefficient (1 = identical distributions) · a group with $n < 10$ is not drawn · x-axis clipped to the 0.5-99.5 percentile, then widened so the WT anchor is always inside · 3 assays ship no WT row
